

Parking Sensor

For my final project, I decided to make a sample parking sensor using Raspberry pi. It will work as a parking sensor. The idea of this park sensor is to show green when you have plenty of room to pull your car forward in parking lot, and then turn red when you should stop. We're going to build this system with our Raspberry Pi, and use some distances that we can easily test.

Components used

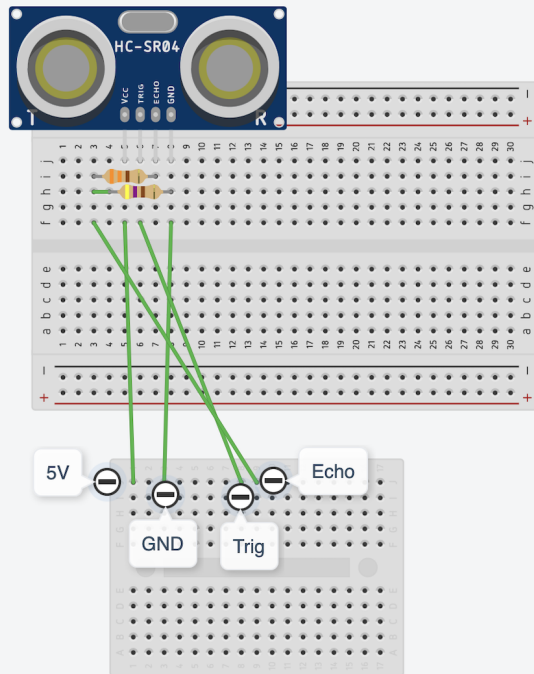

The following components will be used in this project other than Raspberry Pi setup.

1. HC-SR04 Ultrasonic Distance Sensor
2. Led (X2)
3. 330Ω Resistor (X4)
4. Male-Female Jumper Wires
5. Breadboard

Stage 1 - Ultrasonic Distance Sensor

1. Connect ultrasonic distance sensor to breadboard
2. Trigger for the distance sensor is GPIO 24
3. Echo for distance sensor is GPIO 23 using resistor whose one side should be pinned in echo and other side on a breadboard with no sensor pin.
4. Another resistor should be pinned below GND and the pin below the resistor pin of echo

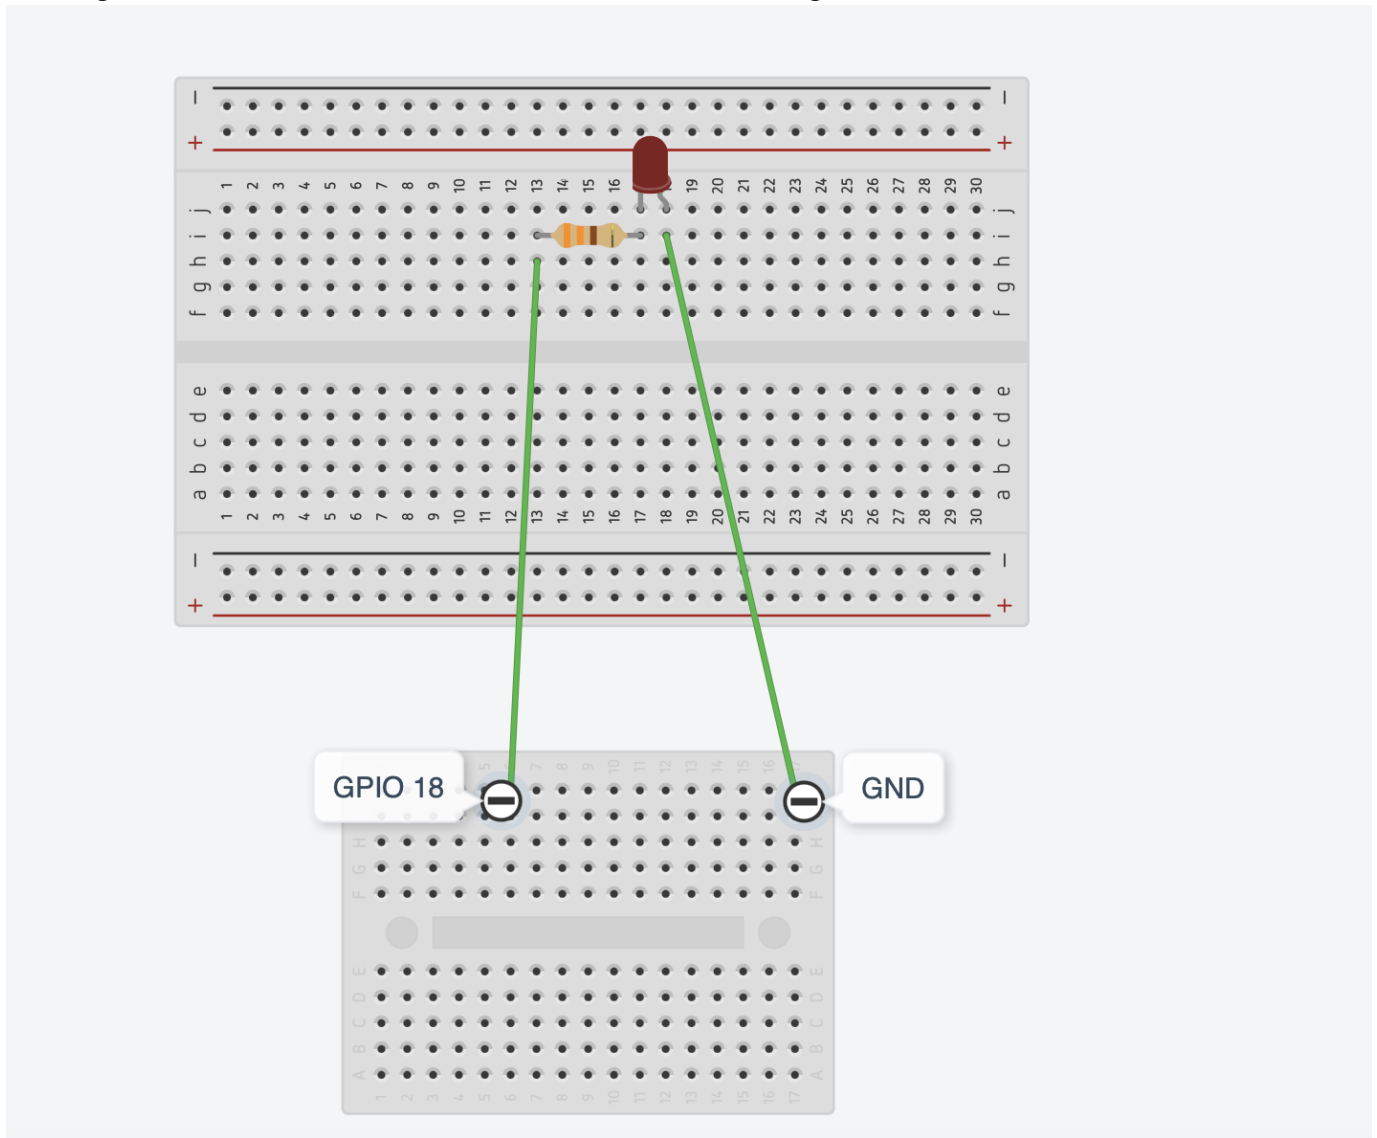

The figure below shows the circuit for ultrasonic distance sensor

Stage 2 - Red LED Light

1. Connect red LED light in the breadbord. Use resistor and cathode into GPIO 18 and anode to GND in Raspberry pi

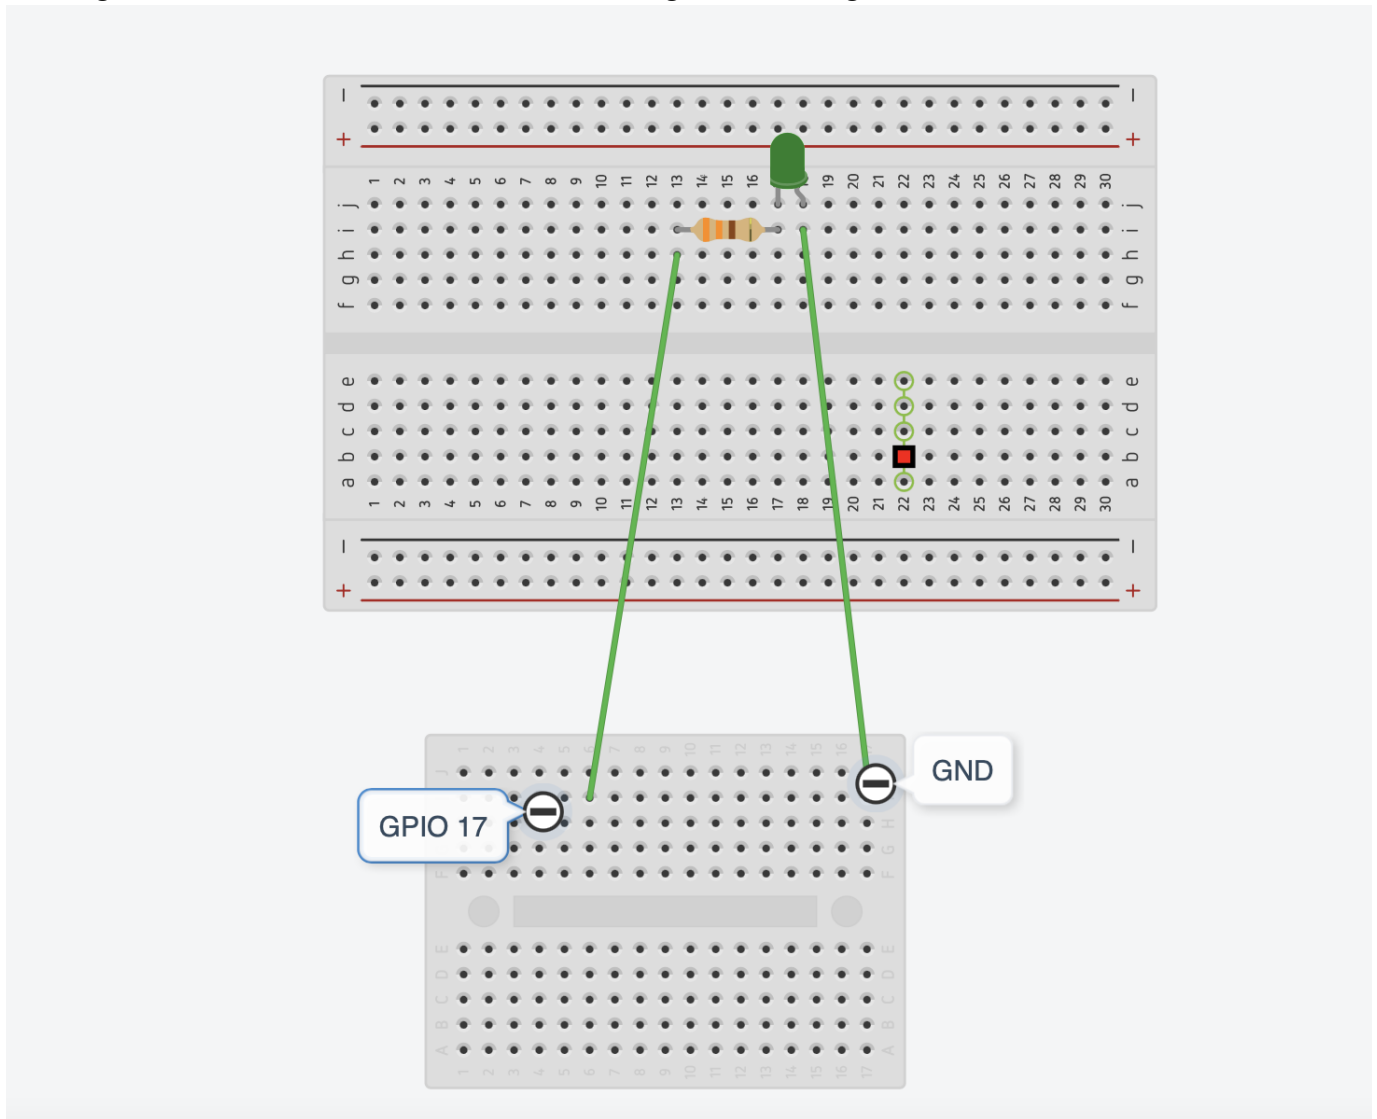

The figure below shows the connection for red LED light

Stage 3 - Green LED Light

1. Connect green LED light in the breadboard. Use resistor and connect cathode into GPIO 17 and anode to GND in Raspberry pi

The figure below shows the connection for green LED light

Final coding section

Open your Raspberry pi and inster the below code:

```
import RPi.GPIO as GPIO
import time

GPIO.setwarnings(False)
GPIO.cleanup()
GPIO.setmode(GPIO.BCM)

TRIG=24
ECHO=23
RED=18
GREEN=17

GPIO.setup(TRIG,GPIO.OUT)
```

```
GPIO.setup(ECHO,GPIO.IN)
GPIO.setup(RED,GPIO.OUT)
GPIO.setup(GREEN,GPIO.OUT)

def red_light():
    GPIO.output(RED, GPIO.HIGH)
    GPIO.output(GREEN, GPIO.LOW)
def green_light():
    GPIO.output(GREEN, GPIO.HIGH)
    GPIO.output(RED, GPIO.LOW)
def get_distance():
    GPIO.output(TRIG, True)
    time.sleep(0.00001)
    GPIO.output(TRIG, False)

    while GPIO.input(ECHO) == False: start = time.time()
    while GPIO.input(ECHO) == True: end = time.time()

    signal_time = end-start
    distance = signal_time / 0.000058
    return distance

while True:
    distance = get_distance()
    time.sleep(1)
    print(distance)

    if distance <= 10:
        red_light()
    else:
        green_light()
```

The image below shows the screenshot for the code

Output

If the object is too close to the sensor a solid red light flashes or the solid green light flashes.
